धनबाद-826004 झारखंड, भारत INDIAN INSTITUTE OF TECHNOLOGY (INDIAN SCHOOL OF MINES) DHANBAD-826004 JHARKHAND, INDIA

This is to certify that the project entitled "BUCKLING ANALYSIS OF FUNCTIONALLY GRADED PLATE" been carried out by AYUSH YADAV (Admission Number 18MT0071) at the Department of Mechanical Engineering Indian Institute of Technology (Indian School of Mines), Dhanbad under the supervision in the partial fulfillment of the requirement of the award of the Degree of Master of Technology in Mechanical Engineering (specialization: Machine Design) during the academic session 2019-2020.

Dr. Md Sikandar Azam

Assistant Professor

Dept. of Mechanical Engg.

Indian Institute of Technology

(Indian School of Mines) Dhanbad

#### **ACKNOWLEDGEMENT**

A person cannot go through life without the help and guidance of others. One is invariably indebted, which may be of physical, mental, physiological or intellectual in nature, knowingly or unknowingly. To enlist all of them is not easy. To repay them even in words is beyond our capabilities.

With recondite honour, I offer our sincerest gratitude to my guide *Dr. Md Sikandar Azam*, Asst. professor, Department of Mechanical Engineering, for his enthusiasm, his inspiration and his great efforts to explain things clearly and simply. He took great pain in going through the entire literature, and made immortal comments and acted as a beacon at each and every step in the accomplishment of this project work.

I extend my heartfelt thanks to *Mr.Piyush Pratap Singh*, Research Scholar, IIT(ISM) Dhanbad for his guidance, continuous support, and cooperation throughout my work.

AYUSH YADAV Admission No – 18MT0071

### **DECLARATION**

I hereby declare that the dissertation entitled "Buckling analysis of Functionally Graded Plate" submitted to INDIAN INSTITUTE OF TECHNOLOGY (INDIAN SCHOOL OF MINES), DHANBAD is a record of original work done by me under the guidance of **Dr. Md. Sikandar Azam**, (Assistant professor) Department of Mechanical Engineering and this work has not been presented anywhere fully or partially for the award of any degree.

Date-02 April. 2020

Place- Dhanbad

AYUSH YADAV Admission no.- 18MT0071

M.Tech (Mechanical Engg.)

Dr. Md Sikandar Azam Guide Assistant Professor Dept. of Mechanical Engg. Indian Institute of Technology (ISM) Dhanbad

### **Abstract**

In this work, the analysis of buckling of plates is conducted to learn the behavior of rectangular plates under biaxial thermo mechanical loading and subjected to different sets of boundary conditions within the framework of classical plate theory. Variational method of weighted residual is used to obtain the generalized form of differential equation. Trial functions denoting the displacement components are expressed in simple algebraic polynomial forms which can handle any sets of boundary conditions. The presented mathematical model omits the limitations regarding edge conditions and is accurate, more accessible, and computationally faster. Rayleigh–Ritz method is used to obtain the generalized solution of the differential equation. A parametric study has been thoroughly conducted focusing on the effects of aspect ratio, nano effect, power law exponent, elastic foundation and loading parameter on nondimensionalised buckling load of plate. It has been observed that the aspect ratio, elastic foundation and power law exponent have great influence on buckling load. New results for nondimensionalised buckling load are incorporated after performing a test of convergence. Comparison with the results from the existing literature are provided for validation.

# Introduction

Plate is a two dimensional element, it means width is comparable to length but the thickness is not comparable to its width and length. Plate is one of the important structural element it has many engineering application such as air bridge, buildings, aircraft wings, big machines base and offshore structures. Most of the structural plates are stronger in tension as compared to compression. Generally compressed plate failure promote the tragic structural failure. So to avoid the failure of whole structure it is very important.

Functionally graded materials are a type of composite that made from two different materials of desires properties, which are impossible to find in a single material. In FGM, the variation of the material properties take place from one end of the material to another end. Now a days FGM used in many engineering field like mechanical engineering, civil, aerospace, nuclear and automotive. With the increasing demand of FGM material in various field, many researches have been done to analyse the behaviour of FGM under different conditions like environment, loading etc. Most of the research models are based on the displacement theories and to find the equilibrium equation they used principal of virtual work.

Based on some research model, the surrounding elastic medium such as Winkler-type and Pasternak-type elastic foundation has a great influence on the analysis of FGM plate. The FGM plate is treated to be rested on the elastic foundation of Winkler and Pasternak, and these parameter precisely considering both the spring and shear effect of elastic foundation. The results found by the researcher in their study using this Winkler and Pasternak foundation model

are desired and accurate. Here, the Winkler and Pasternak coefficient represents the linear springs and the shear effect of the elastic foundation respectively .

#### 1.1. Objective and Scope of Study

The buckling of rectangular FGM plate have been studied by several researches and various results are available based on some boundary conditions. However, a new FGM plate buckling problem where the FGM plate subjected to mechanical loading (biaxial compression), *thermal loading* with uniform and linear rise, FGM plate with size effect (nanoplate) and plate under thermal environment remains to be studied.

The aim of this work is to determine the nondimensional buckling load under thermosmechanical loading with or without size effect. And this study also consists the effect of thermal
environment on the buckling load. The plate have simply supported, clamp, free and mixed
boundary condition. Classical plate theory and principal of virtual work is used to calculate the
equilibrium equation. Further the study consider the effects of various plate parameters aspect
ratios, foundation, size effect, temperature, power law exponent to vary the mechanical
properties of FGM and different boundary condition.

# Chapter 2

# Literature Review

The following literature review will help to know the background information for this research. The literature review target on the thin isotropic FGM plate. In this part the focus will be on the investigation of FGM rectangular plates under different boundary conditions. Navier (1822) first derive the basic equilibrium equation of rectangular plate under lateral load. Saint-Venant (1883) include the axial edge forces and shearing forces and modified that equation. Now this equation become the basis for most of the work on plate stability of plates with various loads and different boundary condition.

Bryan (1891) first consider the plate under biaxial compressive loading with simply supported edge condition (SSSS) by written the deflection as a double Fourier series. Wang(1953) approached that problem by Finite-difference method. Timoshenko and Gere (1961) solved the plate under bi-axial loading with all clamped edge condition (CCCC) by the energy method. Bulson (1970) cited many research works on buckling of plate subjected to biaxial compression. One of them is proper analysis for ESFS plates by using the exact solution of the differential equation of equilibrium. And also added an extra term in equilibrium equation for transverse force. Along one side ranged between simply supported and clamped edge boundary condition it is found the effect of a restraint. In another example it is used two buckling forms, i.e. symmetric and anti-symmetric forms for the calculation of FSFS edge condition, with the help of this research work it is found that the load associated with symmetric buckling forms were much lower than the anti-symmetric form.

FGMs are appropriate for various engineering field and gained intense interest by several researches (Javaheri and Eslami, 2002; Chakraborty et al, 2003; Zenkour and Sobhy, 2010; Zhang, 2013; Pradhan and Chakraverty, 2013; Esfahani et al 2014; Wattanasakulpong and Chaikittiratana, 2015).

Xiang et al. (2003) solved the problem of rectangular plate buckling with internal hinge under biaxial loads with the help of Ritz method. It is used to calculate the buckling factors for rectangular plates of various hinge location, boundary condition and aspect ratios. Hosseini-Hashemi et al. (2008) has worked on the buckling of isotropic plate. In this study they presented the non-dimensional critical buckling loads and mode shape for combination of four different boundary in which two opposite edges are simply supported under biaxial compression. V. Piscopo (2010) investigated the shimpi for thick plate and also recognized FEM as one of the most efficient method for thin plate buckling analysis under different boundaries conditions. Chee-Kiong Chin et al. (1993) conferred a finite element method using thin plate element. This method was capable to calculate the nondimensional buckling load for any arbitrarily shape thin plate member under general loading and boundary condition. MwisamMohammadi, et al. (2010) presented the explicit buckling analysis for thin FGM plate, and the equilibrium equations are obtained by using classical plate theory (CPT) and principal of minimum total potential energy. The resulting differentials are solved for different loading conditions and finally get the non dimensional buckling load.

Na and Kim (2004) examined three-dimensional (3D) thermal buckling analysis for FGM. They investigate the variation of material properties and temperature field in thickness direction using 18- node solid element by FEM. Shariat and Eslami (2005, 2006) performed thermal buckling analysis on geometrical imperfection rectangular FGM plate. They used classical plate theory to drive stability, compatibility and equilibrium equations. Naderi and

Saidi (2011) analysed the buckling of FGM annular sector plate resting on an elastic foundation and provide an analytical solution for that problem. They used Kirchoff's plate theory and energy mathod to drive equilibrium and stability equation. Shariat and Eslami (2007) performed the buckling analysis of thick rectangular FGM plates under thermo- mechanical load using third-order shear deformation plate theory (HSDT). Zhao et al. (2009) used first- order shear deformation theory (FSDT) with the element- free *kp*-Ritz method to performed the buckling analysis under mechanical and thermo-mechanical loading. Lanhe (2004) used FSDT kinematics to drive the equilibrium and stability equations of a moderately thick FGM plate, which material properties varies in thickness direction subjected under thermal loading. Talha and Singh (2011) work on thermomechanical induced vibration characteristics of FGM plates based on modified higher-order shear deformation kinematics. They conclude the effect of volume fraction and temperature field on vibration characteristics of the FGM plates .

Nanoscale is a field of intense interest of several researches in the field of nanomechanics. Therefore, it is very important to consider the influence of small size in the mechanical analysis of nanostructures. The classical continuum elasticity theory is not capable of describing the size influence due to the lack of a material length scale. So, Eringen (Eringen, 1972 and 1983) proposed the nonlocal elasticity theory which is sizedependent continuum theory. According to this theory stress at a reference point is a function of strain of all points of the body. Hence this nonlocal theory (sizedependent) applied to analyse the mechanical response of nanoplates(Ressy, 2007; Prsdhan and Phadikar, 2009; Aydogdu, 2009; Murmu and Adhikari, 2010; Lim et al. 2010; Ke et al. 2014).

Reddy (2000) used third-order shear deformation plate theory and developed a FE model that accounts for the thermomechanical coupling for FGM plate. But, that analysis did not consists the change of material properties due to temperature distribution. Yang and Shen

(2002) presented the vibration characteristics and transient response analysis of FGM plate made of temperature-dependent material in thermal environment. According to the above-mentioned studies, one can notice the influence of various temperature environments on buckling behaviour of functionally graded nanoplate embedded in elastic foundation is not yet conducted .

# **Chapter 3**

# Mathematical modelling

This chapter consists of the derivation of the governing equation for rectangular FGM plate subjected under thermo- mechanical loading and Plate under thermal environment. We consider Classical plate theory and Hamilton principal to drive the equilibrium equation.

#### 3.1. Thin FGM plate subjected under biaxial compression

Consider a thin rectangular FGM plate of dimension, length a, width b, and height h is subjected under biaxial compressive load  $N_x$  and  $N_y$  as shown in figure 2.1. Taking reference plane as mid plane and adopting Cartesian coordinate system. The biaxial loading  $N_x$  and  $N_y$  are parallel to x and y axis respectively.

For thin plate all theories gives the same results so we are adopting classical plate theory here because it is a simplest plate theory.

Assumptions of classical plate theory are:

- a. Thickness of the plate is small as compared to the thickness, it is a case of plain stress.
- b. No stretching in z direction, it means plain strain condition.
- c. Mid plane remain neutral i.e. no stretching in mid plane.
- d. The plane section rotate during bending to remain normal to the neutral surface, and do not distort, so that stresses and strains are proportional to their distance from the neutral surface.
- e. Effect of shearing load is neglected and the load is entirely resisted by the banding moment induced in plate element.

Derivation starts on the behalf of first two assumption, that no stretching in z direction. It means normal stress and strain in z direction are zero. Material properties of FG plate are assumed to vary along the thickness direction according to power-law form as:

$$p(z) = (p_c - p_m) \left(\frac{z}{h} + \frac{1}{2}\right)^k + p_m$$
 3.1

Where  $p_m$  and  $p_c$  denote the value of the material properties of the metal and ceramic ingredient of the FG plate, respectively. Power law exponent (k) is a nonnegative variable parameter. At bottom surface (z=-h/2) of FG plate is pure metal, although the top surface (z=h/2) is pure ceramic and one can get the desirable properties by different value of k. In this case only young's modulus (E) considered as the variable property where as the value of poisson's ratio will remain constant with respect to thickness

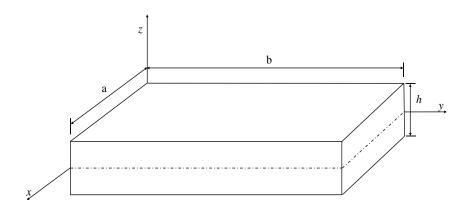

Figure 3.1. The schematic of the isotropic plate

According to the assumption, no stretching along the thickness,

$$\varepsilon_{zz} = 0$$

$$\varepsilon_{zz} = \frac{\partial W}{\partial Z} = 0$$

On integration,

$$W=f(x,y)$$

At the middle plate, z=0, and  $W = W_0$ 

3.4

Now assumption on shear strain of z plane considering equal to zero.

$$\gamma_{zx} = \frac{\partial u}{\partial z} + \frac{\partial w}{\partial x} = 0$$

$$\frac{\partial u}{\partial z} = -\frac{\partial w}{\partial x}$$
 3.5

On integration,

$$u = -z\frac{\partial w}{\partial x} + g(x, y)$$
3.6

And at mid plane z=0, so  $u = u_0$ 

$$g(x, y) = u_o 3.7$$

$$u = u_0 - z \frac{\partial w}{\partial x}$$
 3.8

Similarly,

$$v = v_0 - z \frac{\partial w}{\partial x}$$
 3.9

The displacement field can be represented as

$$u = \begin{cases} u_x(x, y, t) \\ u_y(x, y, t) \\ u_z(x, y, z, t) \end{cases} = \begin{cases} u_0 - z \frac{\partial w(x, y)}{\partial x} \\ v_0 - z \frac{\partial w(x, y)}{\partial y} \\ w(x, y, t) \end{cases}$$

$$3.10$$

Where  $u_x$   $u_y$  and  $u_z$  are displacement along coordinates x, y and z, and w shows the deflection of an arbitrary point in the z-axis on the middle plane.

According to the nonlocal theory of elasticity, stress at a point in a body depends on strains at all other points of that body. According to this assumption, the nonlocal behaviour of a Hookean solid is introduced by the following transformed differential equation.

$$\sigma_{ij}^{(nl)} - \mu \nabla^2 \sigma_{ij}^{(nl)} = \sigma_{ij}^{(l)}$$
3.11

$$\alpha = \left(\frac{e_0 l_{\text{int}}}{l_{\text{ext}}}\right)^2$$
3.12

$$\mu = (l_0 l_{\text{int}})^2 \tag{3.13}$$

Whereas  $\sigma_{ij}^{(nl)}$  and  $\sigma_{ij}^{(l)}$  represent the nonlocal and local stress tensor respectively.  $\mu$  represent the nonlocal parameter.

According to Kirchhoff's assumption, the displacement associated with linear non zero strain is presented as

$$\begin{cases}
\varepsilon_{xx} \\
\varepsilon_{yy} \\
\gamma_{xy}
\end{cases} = \begin{cases}
\frac{\partial u}{\partial x} \\
\frac{\partial v}{\partial y} \\
\frac{\partial u}{\partial y} + \frac{\partial v}{\partial x}
\end{cases} = \begin{cases}
\frac{\partial u_0}{\partial x} - z \frac{\partial^2 w}{\partial x^2} \\
\frac{\partial v_0}{\partial y} - z \frac{\partial^2 w}{\partial y^2} \\
\left(\frac{\partial v_0}{\partial y} + \frac{\partial u_0}{\partial x} - 2z \frac{\partial^2 w}{\partial x \partial y}\right)
\end{cases}$$
3.14

where,  $\mathcal{E}_{xx}$  and  $\mathcal{E}_{yy}$  are normal strains and  $\gamma_{xy}$  is a shear strain. Following the generalized Hook's law, the stress-strain relationship is formulated as:

$$\begin{cases}
\sigma_{xx} \\
\sigma_{yy} \\
\tau_{xy}
\end{cases} = 
\begin{pmatrix}
C_{11} & C_{12} & 0 \\
C_{21} & C_{22} & 0 \\
0 & 0 & C_{66}
\end{pmatrix} 
\begin{pmatrix}
\varepsilon_{xx} \\
\varepsilon_{yy} \\
\gamma_{xy}
\end{pmatrix}$$
3.15

where,  $\sigma_{xx}$  and  $\sigma_{yy}$  are normal stresses and  $\tau_{xy}$  is shear stress in x - y plane. Further,

 $C_{11}$ ,  $C_{12}$ ,  $C_{22}$ ,  $C_{66}$  are

$$C_{11} = \frac{E(Z)}{(1-v^2)}$$
  $C_{12} = \frac{vE(Z)}{(1-v^2)}$   $C_{66} = \frac{E(Z)}{2(1+v)}$  3.16

Stress and moments are

$$\begin{cases}
N_{x} \\
N_{y} \\
N_{xy}
\end{cases} = \int_{-h/2}^{h/2} \begin{cases} \sigma_{x} \\
\sigma_{y} \\
\tau_{xy}
\end{cases} dz$$

$$\begin{cases}
M_{x} \\
M_{y} \\
M_{xy}
\end{cases} = \int_{-h/2}^{h/2} z \begin{cases} \sigma_{x} \\
\sigma_{y} \\
\sigma_{xy}
\end{cases} dz$$
3.17

Using the principle of virtual work, the equation of motion of rectangular plate is derived and written as

$$\frac{\partial N_{xx}}{\partial x} + \frac{\partial N_{xy}}{\partial x} = 0$$

$$\frac{\partial N_{xx}}{\partial x} + \frac{\partial N_{xy}}{\partial x} = 0$$

$$\frac{\partial^{2} M_{x}}{\partial^{2} x^{2}} + \frac{\partial^{2} M_{y}}{\partial^{2} y^{2}} + \frac{\partial^{2} M_{xy}}{\partial x \partial y} + \frac{\partial}{\partial x} \left( N_{x} \frac{\partial w}{\partial x} \right) + \frac{\partial}{\partial y} \left( N_{y} \frac{\partial w}{\partial y} \right)$$

$$+ \frac{\partial}{\partial x} \left( N_{xy} \frac{\partial w}{\partial y} \right) + \frac{\partial}{\partial y} \left( N_{xy} \frac{\partial w}{\partial x} \right) + q - k_{w} + k_{p} \left( \frac{\partial^{2} w}{\partial x^{2}} + \frac{\partial^{2} w}{\partial y^{2}} \right) = 0$$
3.18

Using equation (3.15) - (3.17), the bending moments resultants of plate in terms of flexural rigidities (bending stiffness) and displacement field are expressed as:

$$M_{ij}^{(nl)} - \mu \nabla^2 M_{ij}^{(nl)} = M_{ij}^{(l)}$$

$$\begin{cases}
M_x \\
M_y \\
M_{xy}
\end{cases} = \begin{bmatrix}
D_{11} & D_{12} & 0 \\
D_{21} & D_{22} & 0 \\
0 & 0 & D_{66}
\end{bmatrix} \begin{cases}
\frac{\partial^2 w}{\partial x^2} \\
\frac{\partial^2 w}{\partial y^2} \\
\frac{\partial^2 w}{\partial xy}
\end{cases}$$
3.19

The flexural rigidities is defined in terms of coefficient of stiffness as

$$D_{11} = \int_{\frac{-h}{2}}^{\frac{h}{2}} C_{11} Z^2 dz , \qquad D_{12} = \int_{\frac{-h}{2}}^{\frac{h}{2}} C_{12} Z^2 dz \qquad \text{and} \qquad D_{66} = \int_{\frac{-h}{2}}^{\frac{h}{2}} C_{66} Z^2 dz$$
 3.20

With the help of equations (3.15), (3.17), (3.18) and (3.19), and assuming modal equation,

 $w = W(x, y)e^{i\omega t}$ , the following decoupled equilibrium equation will be obtained for rectangular plate.

$$D_{11} \frac{\partial^{4} W}{\partial x^{4}} + 2(D_{12} + 2D_{66}) \frac{\partial^{4} W}{\partial x^{2} \partial y^{2}} + D_{22} \frac{\partial^{4} W}{\partial y^{4}}$$

$$- (1 - \mu \nabla^{2}) \left[ q_{0} - k_{w} W + k_{p} \left( \frac{\partial^{2} W}{\partial x^{2}} + \frac{\partial^{2} W}{\partial y^{2}} \right) \right]$$

$$\left( \frac{\partial}{\partial x} \left( N_{xx} \frac{\partial W}{\partial x} \right) + \frac{\partial}{\partial y} \left( N_{yy} \frac{\partial W}{\partial y} \right) + \frac{\partial}{\partial x} \left( N_{xy} \frac{\partial W}{\partial y} \right) + \frac{\partial}{\partial y} \left( N_{yx} \frac{\partial W}{\partial x} \right) \right) = 0$$

$$3.21$$

### 3.2. Solution procedure

The calculus of variation is a branch of mathematics wherein the stationary property of function of function, namely, a functional, is studied.

It is well known that the basis of variational formulation is the principle of minimum total potential energy. The principle of minimum total potential energy is valid under the assumption that stress at a point can be uniquely defined in terms of the strain at that point.

Here an inverse approach is taken to reach to quadratic form of the governing equation.

This quadratic functional can be then used as a basis for different numerical solution such as Rayleigh-Ritz and finite element methods.

#### 3.2.1. Weak formulation

The partial differential equation developed in equation (3.21) is the strong form of the governing system of equation for buckling of rectangular FG plate since obtaining the exact solution for a strong form of the system equation is usually difficult for practical engineering problems, because at the end of solution it forms inconsistence form of solution. A weak form of the system of equations is usually created for solution. The weak form is often an integral form and requires a weaker continuity on the field variables in contrast to the strong form. The weak form of the system of equations is usually created using one of the energy principles or weighted residual methods.

So by weighted residual method

$$\int_{R} k(\nabla^4 W + q) = 0$$
3.22

K=weight function

$$\iint_{R} \left\{ D_{11} \frac{\partial^{4}W}{\partial x^{4}} + 2(D_{12} + 2D_{66}) \frac{\partial^{4}W}{\partial x^{2} \partial y^{2}} + D_{22} \frac{\partial^{4}W}{\partial y^{4}} - (1 - \mu \nabla^{2}) \left[ q_{0} - k_{w}W + k_{p} \left( \frac{\partial^{2}W}{\partial x^{2}} + \frac{\partial^{2}W}{\partial y^{2}} \right) \right] \right. \\ \left. \left( \frac{\partial}{\partial x} \left( N_{xx} \frac{\partial W}{\partial x} \right) + \frac{\partial}{\partial y} \left( N_{yy} \frac{\partial W}{\partial y} \right) + \frac{\partial}{\partial x} \left( N_{xy} \frac{\partial W}{\partial y} \right) + \frac{\partial}{\partial y} \left( N_{yx} \frac{\partial W}{\partial x} \right) \right) \right\} K dx dy = 0$$

With the help of Gauss and Green theorem breaking this residual form into integral of region and boundary.

$$\iint\limits_R \dot{\prod}(x,y) dx dy = 0$$

$$\begin{split} \dot{E} &= D_{11} \left( \frac{\partial^{2}W}{\partial x^{2}} \frac{\partial^{2}K}{\partial y^{2}} \right) + D_{12} \left( \frac{\partial^{2}W}{\partial x^{2}} \frac{\partial^{2}K}{\partial y^{2}} + \frac{\partial^{2}W}{\partial y^{2}} \frac{\partial^{2}K}{\partial x^{2}} \right) + D_{22} \left( \frac{\partial^{2}W}{\partial y^{2}} \frac{\partial^{2}K}{\partial y^{2}} \right) + \left( 4D_{66} \frac{\partial^{2}W}{\partial x \partial y} \frac{\partial^{2}K}{\partial x \partial y} \right) \\ &+ k_{w} \left[ WK + \mu \left( \frac{\partial W}{\partial x} \frac{\partial K}{\partial x} + \frac{\partial W}{\partial x} \frac{\partial K}{\partial x} \right) \right] \\ &+ k_{p} \left[ \frac{\partial W}{\partial x} \frac{\partial K}{\partial x} + \frac{\partial W}{\partial x} \frac{\partial K}{\partial x} + \mu \left( \frac{\partial^{2}W}{\partial x^{2}} \frac{\partial^{2}K}{\partial x^{2}} + 2 \frac{\partial^{2}W}{\partial x \partial y} \frac{\partial^{2}K}{\partial y \partial x} + \frac{\partial^{2}W}{\partial y^{2}} \frac{\partial^{2}K}{\partial y^{2}} \right) \right] \end{split}$$

$$\dot{\tilde{F}} = N_{\boldsymbol{X}} \bigg( \frac{\partial \boldsymbol{W}}{\partial \boldsymbol{x}} \frac{\partial \boldsymbol{K}}{\partial \boldsymbol{x}} + \mu \bigg( \frac{\partial^2 \boldsymbol{W}}{\partial \boldsymbol{x}^2} \frac{\partial^2 \boldsymbol{K}}{\partial \boldsymbol{x}^2} + \frac{\partial^2 \boldsymbol{W}}{\partial \boldsymbol{x} \partial \boldsymbol{y}} \frac{\partial^2 \boldsymbol{K}}{\partial \boldsymbol{x} \partial \boldsymbol{y}} \bigg) \bigg) + N_{\boldsymbol{y}} \bigg( \frac{\partial \boldsymbol{W}}{\partial \boldsymbol{y}} \frac{\partial \boldsymbol{K}}{\partial \boldsymbol{y}} + \mu \bigg( \frac{\partial^2 \boldsymbol{W}}{\partial \boldsymbol{y}^2} \frac{\partial^2 \boldsymbol{K}}{\partial \boldsymbol{y}^2} + \frac{\partial^2 \boldsymbol{W}}{\partial \boldsymbol{x} \partial \boldsymbol{y}} \frac{\partial^2 \boldsymbol{K}}{\partial \boldsymbol{x} \partial \boldsymbol{y}} \bigg) \bigg)$$

The Rayleigh Ritz functions obviate the tedious task of choosing the form of the infinite series or trigonometric or algebraic functions to suit the conditions of support along the edges. These functions are made from the product of a basic function and a set of orthogonal polynomials whose degree may be increased until the desired accuracy is achieved. The basic function is defined by the product of equations of the specified boundary shape of the plate raised to the power of either 0, 1 or 2 corresponding to free, simply supported and clamped edges, respectively.

$$W(x, y) = \sum_{i} C_{i} \phi_{i}(x, y)$$

$$3.25$$

 $C_j$ =unknown coefficient

 $\phi_i$  =Algebraic function

It is well known that 'The determination of the weak form is equivalent to the minimization of the quadratic function or minimization of the total potential energy .

$$B(K,W) = l(k)$$
3.26

To satisfy the essential boundary condition  $K \longrightarrow \delta W$ 

Now this weak form become,

$$B(\delta W, W) = l(\delta W)$$
 3.27

$$B(\delta W, W) = \int \left(\frac{\partial \delta W}{\partial x} \frac{\partial w}{\partial x} + \frac{\partial \delta W}{\partial x} \frac{\partial w}{\partial x}\right) d\Omega$$
3.28

$$B(\delta W, W) = \delta \int \frac{1}{2} \left( \left( \frac{\partial w}{\partial x} \right)^2 + \left( \frac{\partial w}{\partial x} \right)^2 \right) d\Omega$$
3.29

$$B(\delta W, W) = \frac{\delta}{2} (B(W, W))$$
3.30

$$\frac{\delta}{2} (B(W, W)) - \delta l(W) = 0$$
 3.31

$$\frac{1}{2}\Big[\Big(B\big(W,W\big)\Big) - l(W)\Big] = 0$$

$$E = \frac{1}{2} [A + B + C]$$

$$A = D_{11} \left( \frac{\partial^{2} W}{\partial x^{2}} \right)^{2} + 2D_{12} \left( \frac{\partial^{2} W}{\partial x^{2}} \frac{\partial^{2} W}{\partial y^{2}} \right) + D_{22} \left( \frac{\partial^{2} W}{\partial y^{2}} \right)^{2} + \left( 4D_{66} \left( \frac{\partial^{2} W}{\partial x \partial y} \right)^{2} \right)$$

$$B = k_{w} \left\{ W^{2} + \mu \left( \left( \frac{\partial W}{\partial x} \right)^{2} + \left( \frac{\partial W}{\partial y} \right)^{2} \right) \right\}$$

$$C = k_{p} \left\{ \left( \frac{\partial W}{\partial x} \right)^{2} + \left( \frac{\partial W}{\partial y} \right)^{2} + \mu \left( \left( \frac{\partial^{2} W}{\partial x^{2}} \right)^{2} + \left( \frac{\partial^{2} W}{\partial y^{2}} \right)^{2} + \left( \frac{\partial^{2} W}{\partial x \partial y} \right)^{2} \right) \right\}$$

$$F = \frac{1}{2} [D + G]$$

$$D = N_x \left[ \left( \frac{\partial W}{\partial x} \right)^2 + \mu \left( \left( \frac{\partial^2 W}{\partial x^2} \right)^2 + \left( \frac{\partial^2 W}{\partial x \partial y} \right)^2 \right) \right]$$

$$G = N_y \left[ \left( \frac{\partial W}{\partial y} \right)^2 + \mu \left( \left( \frac{\partial^2 W}{\partial y^2} \right)^2 + \left( \frac{\partial^2 W}{\partial x \partial y} \right)^2 \right) \right]$$
3.34

Now put  $W(x, y) = \sum_{i} C_{ij} \phi_{ij}(x, y)$ 

$$\phi_i(x, y) = \varphi \tau_i(x, y) \tag{3.35}$$

$$\varphi = x^{p} y^{q} (x - a)^{r} (y - b)^{s}$$
3.36

$$\tau_i(x, y) = (1, x, y, x^2, xy, y^2, x^3, x^2y, y^3, x^4, x^2y^2, y^4, \dots)$$
3.37

Where p, q, r and s are exponent, which controls different edge conditions, the parameter p= 0, 1 or 2 denotes that the edge is subjected to Free (F) S (simply supported) or C (clamped) support. Further, the partial derivative of Eqs (3.33) and (3.34) w.r.t unknown constant is taken which results in eq. (3.38)

$$([K]_{nxn} - \lambda_{b}[M]_{nxn})\{\Delta\} = 0$$

$$3.38$$

where,  $\{\Delta\}$  is a coefficient column vector, [K] and [M] are stiffness matrix due to strain energy, stiffness matrix due to potential energy and  $\lambda_b$  denotes non-dimensional mechanical buckling parameters expressed as  $\lambda_b = \frac{|N_x|a^2}{D_c}$ . The uniform in-plane compressive loading  $N_x = N_y = -N$  and  $N_{xy} = 0$ . Where as the  $D_c$  is the flexural rigidity,  $D_c = \frac{E_c h^3}{12(1-\nu^2)}$  3.39

### 3.3. Thermal Buckling

To find the critical buckling temperature of the FGM plate subjected to thermal loading, there is a need to compute the pre-buckling thermal forces. To achieve this, the method of Meyers and Hyer [35] are employed. The resultant of pre-buckling load of plate subject to thermal load is given by [36] as

$$N = \int_{-h/2}^{h/2} \left[ \frac{E(z,T)}{1-\nu} \alpha(z,T) \Psi dz \right]$$
 3.40

Where  $\alpha$  is a coefficient of thermal expansion and  $\Phi$  is the type of temperature distribution through-thickness. For the different thermal distributions different functions of  $\Phi$  are considered, which are given as

For Uniform Temperature rise

Let an FGM nanoplate at a reference temperature  $T_i$ , the temperature is uniformly raised to final value  $T_f$ , which the temperature change is

$$\Delta T = T_f _T T_i$$

$$\Psi = \Delta T$$
3.41

For Linear Temperature rise

For a thin enough FGM plate the temperature distribution can be assumed to linear variation through the thickness as follows (Javaheri and Eslami, 2002): 3.42

$$\Psi = \frac{\Delta T}{h} \left( z + \frac{h}{2} \right) + T_m$$
  
$$\Delta T = T_C - T_m$$

Whereas  $T_c$  = Temperature of the ceramic rich surface.  $T_m$  = Temperature of the metal rich surface.

Following the procedure as above,  $\Delta T$  can be obtained. The critical buckling temperature difference represented as  $\Delta T_{cr}$  are reported here which are the lowest values

### 3.4. Buckling in thermal environment

The derivation of the generalised equation of thin FGM rectangular plate already discuss in the starting of this chapter. The Objective of this sub chapter is to study the power law variation of the temperature dependent material properties for the convergence of the results for the FG plate in thermal environment.

Here we are discuss the two different cases of the temperature variation and its effect on the mechanical properties on FG plate. The variation of temperature only occurs in thickness direction.

The material properties of FG material i.e. Young modulus, poisson ratio and thermal expansion coefficient are nonlinear function of temperature as study presented by J.N.Reddy (1998) and H.S.Shen (2002).

$$P(T) = P^{T}_{0} \left( P_{-1}^{T} T^{-1} + 1 + P_{1}^{T} T^{1} + P_{2}^{T} T^{2} + P_{3}^{T} T^{3} \right)$$

$$3.43$$

Where  $T = T_0 + \Delta T(z)$ , denotes the environmental temperature and  $T_0$  is the room temperature, and  $P_{-1}^T$ ,  $P_0^T$ ,  $P_1^T$ ,  $P_2^T$  and  $P_3^T$  are the constant coefficients in the cubic expression of the respective material property.

We have already discuss the CPT and its assumptions in the starting of this chapter, in this subchapter we are presented the effect of temperature variation on the mechanical properties and these effects of buckling load parameter. So by Hooks law the stress strain relationship can be represented as:

$$\begin{cases}
\sigma_{xx} \\
\sigma_{yy} \\
\tau_{xy}
\end{cases} = 
\begin{pmatrix}
C_{11} & C_{12} & 0 \\
C_{21} & C_{22} & 0 \\
0 & 0 & C_{66}
\end{pmatrix} 
\begin{bmatrix}
\varepsilon_{xx} \\
\varepsilon_{yy} \\
\gamma_{xy}
\end{bmatrix}$$
3.44

where,  $\sigma_{xx}$  and  $\sigma_{yy}$  are normal stresses and  $\tau_{xy}$  is shear stress in x - y plane. Further,  $C_{11}, C_{12}, C_{22}, C_{66}$  are

$$C_{11} = \frac{E(z,T)}{\left(1 - \nu(z,T)^{2}\right)} \qquad C_{12} = \frac{\nu(z,T)E(z,T)}{\left(1 - \nu(z,T)^{2}\right)} \qquad C_{66} = \frac{E(z,T)}{2\left(1 + \nu(z,T)\right)} \qquad 3.45$$

Now the expression of Strain energy and potential energy for the thin rectangular FG plate in thermal environment can be expressed as

$$E_{TH} = \frac{1}{2} [A + B + C]$$

$$A = A_1 + A_2$$

$$A_1 = \left(D^T_{11} + D^T_{12}\right) \left[\left(\frac{\partial^2 W}{\partial x^2}\right)^2 + \left(\frac{\partial^2 W}{\partial y^2}\right)^2 + 2\left(\frac{\partial^2 W}{\partial x \partial y}\right)^2\right]$$

$$A_2 = \left(A^T_{11} + A^T_{12}\right) \left[\left(\frac{\partial^2 W}{\partial x^2}\right)^2 + \left(\frac{\partial^2 W}{\partial y^2}\right)^2\right]$$

$$B = k_w \left\{W^2 + \mu \left(\left(\frac{\partial W}{\partial x}\right)^2 + \left(\frac{\partial W}{\partial y}\right)^2\right)\right\}$$

$$C = k_p \left\{\left(\frac{\partial W}{\partial x}\right)^2 + \left(\frac{\partial W}{\partial y}\right)^2 + \mu \left(\left(\frac{\partial^2 W}{\partial x^2}\right)^2 + \left(\frac{\partial^2 W}{\partial y^2}\right)^2\right) + \left(\frac{\partial^2 W}{\partial x \partial y}\right)^2\right\}$$

The flexural rigidities is defined in terms of coefficient of stiffness as:

$$D_{11} = \int_{\frac{-h}{2}}^{\frac{h}{2}} C_{11} Z^2 \alpha \Delta T dz \qquad \text{and} \qquad D_{12} = \int_{\frac{-h}{2}}^{\frac{h}{2}} C_{12} Z^2 \alpha \Delta T dz \qquad 3.47$$

$$A_{11} = \int_{\frac{-h}{2}}^{\frac{h}{2}} C_{11} \alpha \Delta T dz$$
 and  $A_{12} = \int_{\frac{-h}{2}}^{\frac{h}{2}} C_{12} \alpha \Delta T dz$  3.48

$$F = \frac{1}{2} [D + G]$$

$$D = N_x \left[ \left( \frac{\partial W}{\partial x} \right)^2 + \mu \left( \left( \frac{\partial^2 W}{\partial x^2} \right)^2 + \left( \frac{\partial^2 W}{\partial x \partial y} \right)^2 \right) \right]$$

$$G = N_y \left[ \left( \frac{\partial W}{\partial y} \right)^2 + \mu \left( \left( \frac{\partial^2 W}{\partial y^2} \right)^2 + \left( \frac{\partial^2 W}{\partial x \partial y} \right)^2 \right) \right]$$
3.49

Now we are considering the effect of both biaxial compression and thermal environment on the thin FG plate, so the total strain energy can be presented as:

$$E_{eff} = E + E_{th}$$
 3.50

By equating the both differential equation of strain energy and potential energy we can get the Buckling load 'N' with the help of Ritz method.

$$([K]_{nxn} - \lambda_{b}[M]_{nxn})\{\Delta\} = 0$$

$$3.51$$

where,  $\{\Delta\}$  is a coefficient column vector, [K] and [M] are stiffness matrix due to strain energy, stiffness matrix due to potential energy and  $\lambda_b$  denotes non-dimensional mechanical buckling parameters expressed as  $\lambda_b = \frac{|N_x|a^2}{D_c}$ .

# Chapter 4

# Results and Discussions

We have considered different BCs for the FG plates. Here, the flow of BCs is demonstrated in Fig. 4.1. For example, if we consider the edge support SCSF, then 1 is meant for simply supported (S) and accordingly 2, 3 and 4 represent clamped (C), simply supported (S), completely free (F) edge conditions respectively. In Fig. 4.1 for Lévy plates, 1 and 3 are always kept to be simply supported and other edges 2 and 4 vary as per different BCs.

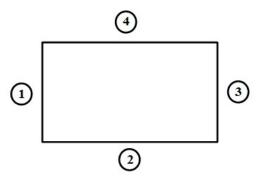

Figure 4. 1 The flow of various combinations of boundary supports in FG plate

The functionally graded plate is considered to be made up of Aluminium and Zirconium. The top and
bottom layers of the plate are ceramics, and metallic respectively. The metal and ceramics that are
employed as contributing materials of the FGEP are (table 1).

Table 4.1 Material Properties of the constituents of FGEP

Properties	Aluminium (Metal)	ZrO <sub>2</sub> – I (Ceramic)
E	70 Gpa	151 Gpa
ν	0.3	0.3
ρ	$2700 \text{ Kg/m}^3$	$3000 \text{ Kg/m}^3$

### 4.1. Convergence

The convergence of non-dimensional buckling of plates (k = 0 in case of FG plates) has been performed in Table 4.2. The convergence of non-dimensional frequencies may be achieved by increasing the number of polynomials (n) in the displacement component.

BC	Polynomials	$\lambda_1$	λ2	λ3	λ4

### 4.2. Comparison

The comparison of the computed result is done with the published one and presented in table 4.3. From the validation, it may be noticed that present results are in excellent agreement with the available literature, irrespective of the elastic foundations and boundary support considered.

#### 4.3. Numerical Results

#### 4.3.1. Parameteric Effect

The effect of various parameters on buckling modes of FG plates resting on Winkler Pasternak Foundation may be observed in Tables 4.4 and 4.5 with different combination of boundary conditions. The important results in Tables 4.4 and 4.5 are summarized as below:

- Irrespective of the elastic foundations and edge support, it can easily be noticed that the buckling load follow the ascending behavior with increase in a/b as shown in the graph.
- Irrespective of k,  $k_w$  and kp assumed, it can also be observed that second non-dimensional buckling load for CCCC and SSSS square FG plates are coinciding with the respective third mode frequencies. But no coincidence can be observed for natural frequencies of rectangular FG plates (a/b $\neq$ 1). This proposition may be true because of the identical edge supports at all edges of the FG square plate.
- Looking into these computations, we may draw the conclusions that the buckling loads are decreasing with the increasing values of k.
- It is evident that non-dimensional buckling load are increasing with increase in foundation parameters ( $k_w$  &  $k_p$ ) regardless of the aspect ratio and power-law index considered. Although the effect of variation of  $k_p$  dominates over  $k_w$ .

### **4.3.2.** Temperature Effect

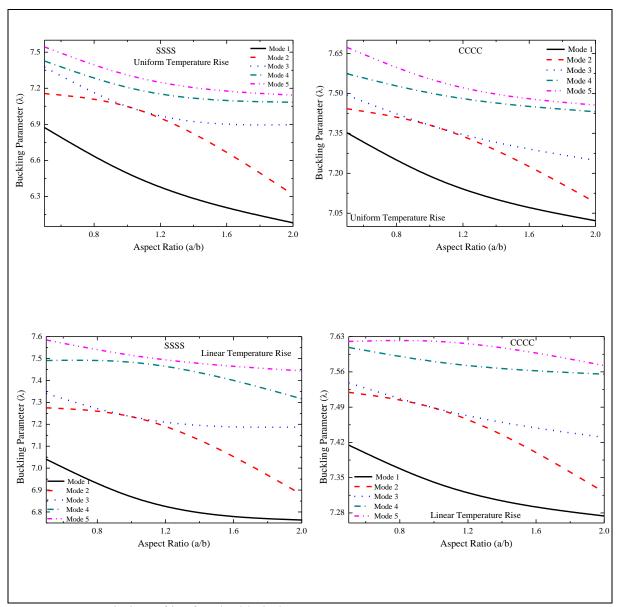

Figure 4.1 Variation of  $\lambda$  of embedded plate for different a/b with k=1,  $k_w$ =50 and  $k_p$ =100,  $\Delta T$ =300.

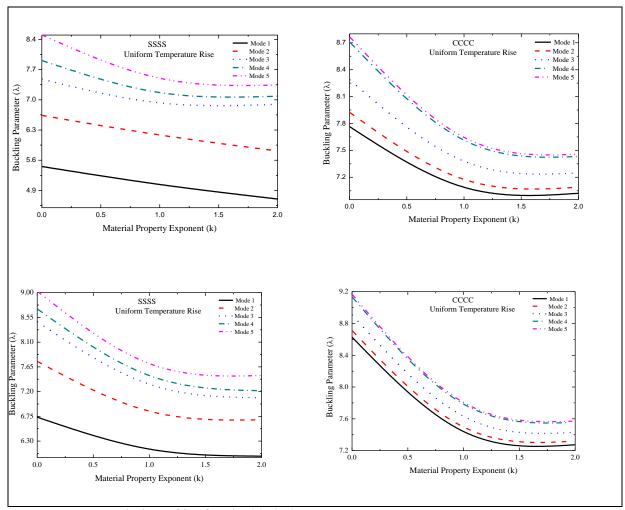

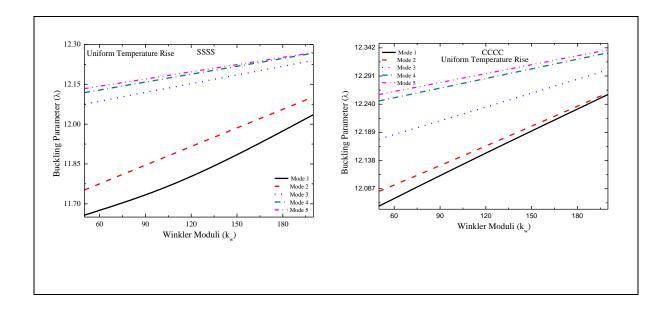

Figure 4.2. Variation of  $\lambda$  of embedded plate for different k with a/b=2,  $k_w$ =50 and  $k_p$ =100,  $\Delta T$ =300.

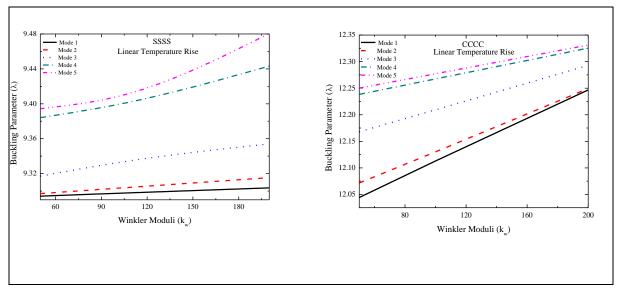

Figure 4.3. Variation of  $\lambda$  of embedded plate with  $k_w$  for with k=1, a/b=2 and  $k_p=100$ ,  $\Delta T=300$ .

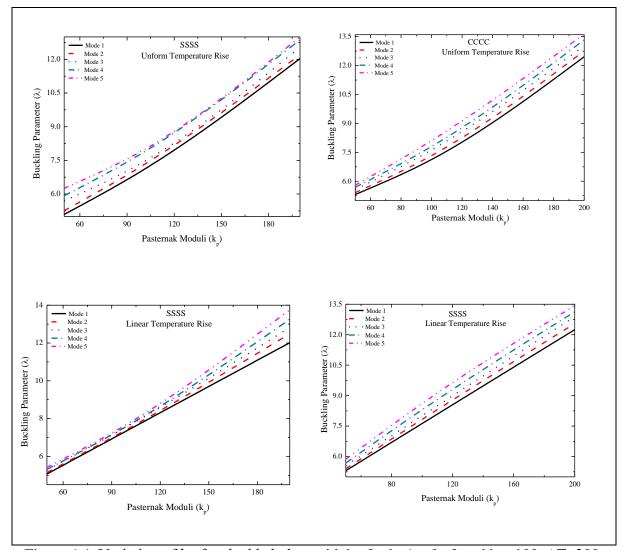

Figure 4.4 Variation of  $\lambda$  of embedded plate with  $k_w$  for k=1, a/b=2 and  $k_w=100$ ,  $\Delta T=300$ .

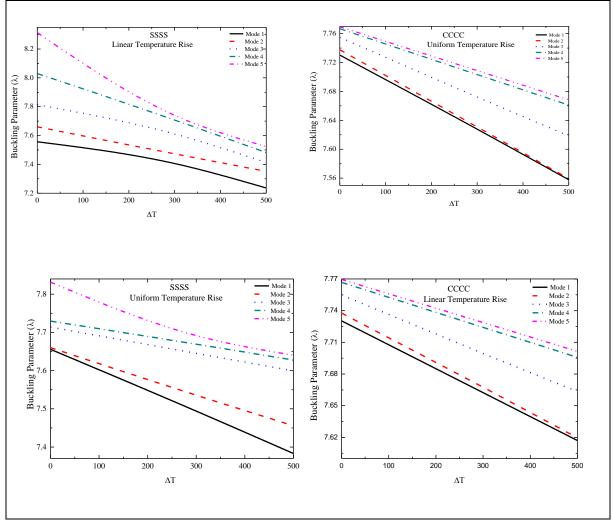

Figure 4.5. Variation of  $\lambda$  of embedded plate with  $\Delta T$  for a/b=2, k=1, k<sub>w</sub>=50 and k<sub>p</sub>=100. In this section, effect of temperature on buckling parameter ( $\lambda$ ) and frequency parameter of FGP in are plotted in figures 4.1 – 4.5. CCCC and SSSS edge constraints are taken into account for the analysis. Effect of the thermal environment are summarized as.

- 1. Irrespective of the edge support and thermal state,  $\lambda$  of an embedded plate decrease with an increase in the aspect ratio. The reason is that the plate loses it's stiffness in a thermal environment.
- The second nondimensional buckling load coincides with the third for a FG square plate irrespective of the thermal condition but no coincidence can be observed for natural frequencies of rectangular FG plates.

# Chapter 5

# **Conclusions**

The thesis is concerned with the buckling of FG rectangular plate resting on the elastic foundation. The plate has four edges with simply supported, clamped, free and their combination. The tedious task of solving the infinite series of trigonometric functions for edge constraints is obviated by the Rayleigh-Ritz and orthogonal algebraic polynomials. These polynomials are capable of handling any configurations of edge constraints simultaneously and efficiently. Also, there is no requirement of generation of mesh, and thus large degrees of freedom can be attained.

The buckling solution constitute of different solution combination depending on various boundary condition, aspect ratios, effect of nano scale, the power law exponent, the temperature and foundation and the influence of these factors are presented in graphs. It is found that in thermal environment the less buckling load required as compared with normal environment, it is obvious because on heating the material getting soft. Our research should be useful for the engineers designing the plated walls under heating environment and subjected to various boundary conditions.

Furthermore, from this analysis, the following can be concluded:

- With increasing a/b of plate, the thermal buckling load of plate increases.
- The 2<sup>nd</sup> and 3<sup>rd</sup> mode of mechanical buckling parameters are same for the case of square plate under clamped and simply supported boundary condition.
- Effect of temperature rise is nominal
- On increasing k buckling load decreases.
